Abstract— Bronchial Asthma is a public health problem in childhood. Allergic Rhinitis (AR) is a very common co-morbidity with Bronchial Asthma. So this study was conducted on 250 Primary School Children to find prevalence of Bronchial asthma and Allergic Rhinitis and their association. It was observed from this study that 17.2% of children were having Bronchial asthma and 20.4% were found to have allergic Rhinitis. Co morbidity of Bronchial Asthma with Allergic Rhinitis was observed in 11.6 % of these cases. It was also observed that Bronchial Asthma was observed significantly more in males than females and children of walled city than outer city. So it was concluded form this study that chances of occurring Allergic Rhinitis is significantly more with Bronchial Asthma than the chances of Bronchial Asthma with Allergic Rhinitis

Keywords— Bronchial Asthma, Allergic Rhinitis, School Children

I. INTRODUCTION

Asthma is a common long term inflammatory disease of the airways of the lungs.¹ It is characterized by variable and recurring symptoms, reversible airflow obstruction, and bronchospasm.² Symptoms include episodes of wheezing, coughing, chest tightness, and shortness of breath.³ These episodes may occur a few times a day or a few times per week. Depending on the person they may become worse at night or with exercise.¹

Asthma is thought to be caused by a combination of genetic and environmental factors.⁴ Environmental factors include exposure to air pollution and allergens.¹ Other potential triggers include medications such as aspirin and beta blockers.¹ Diagnosis is usually based on the pattern of symptoms, response to therapy over time, and spirometry.⁵ Asthma is classified according to the frequency of symptoms, forced expiratory volume in one second (FEV1), and peak expiratory flow rate.⁶ It may also be classified as atopic or non-atopic where atopy refers to a predisposition toward developing a type 1 hypersensitivity reaction.⁷,⁸

Childhood Bronchial Asthma varies widely from country to country. At the age of six to seven years, the prevalence ranges from 4 to 32%. The same range holds good for ages 13 and 14. UK has the highest prevalence of severe Bronchial Asthma in the world.⁹ It has also increased the number of preventable hospital emergency visits and admissions. Apart from being the leading cause of hospitalization for children, it is one of the most important chronic conditions causing elementary school absenteeism.¹⁰,¹¹ Childhood Bronchial Asthma has multifactor causation. Geographical location,
environmental, racial, as well as factors related to behaviors and life-styles are associated with the disease. 12,13

Asthma and allergic rhinitis (AR) co-morbidity refers to the association between asthma and allergic rhinitis. This is due to their physiopathological, epidemiological, and clinical similarities. It is well known that patients with AR have changes in the bronchial mucosa despite the absence of asthma symptoms. Alternatively, patients with asthma have eosinophilic infiltrates in nasal mucosa despite the absence of AR symptoms. The fact that, asthma and AR are manifestations of the same inflammatory disease affecting the entire airway are further suggested by the clinical improvement of asthma when AR is treated.

Epidemiologically, there have been reports – mostly in ambulatory-based studies – showing high prevalence rates of AR in asthmatic patients14, with rates varying between 30-90%. However, population-based studies on the prevalence rates of asthma/AR co-morbidity are still scarce.

So this study was conducted to in Primary School Children in Dausa City to find out association between Bronchial asthma and Allergic Rhinitis.

II. METHODOLOGY

This cross-sectional study was conducted on Primary School Children to find out association between Bronchial asthma and Allergic Rhinitis in Dausa City (Rajasthan) India.

2.1 Sample Size

Sample size was calculated 233 subject at 95% confidence limit and 20% relative allowable error assuming 30% prevalence of Bronchial asthma in children. So for study purpose 250 Primary School Children were included in this study.

2.2 Study Population

Five schools were selected randomly among Primary Schools having strength more than >50 students. From each of identified school, 10 students were chosen from each of I to V class. These 10 students were also chosen randomly through their roll numbers. Thus form every school 50 children were selected, so total 250 children were included in this survey.

2.3 Study Tools

A predesigned proforma is being used for the study. This proforma (Annexure 1) is divided into two parts:

Part I – This part is having introductory data of the children.

Part II – Questionnaire: Pre designed validated questionnaire15 containing various questions pertaining to asthma and allergic rhinitis were distributed. Students and parents were explained by researcher in detail regarding the questions and how to fill the questionnaire. Questionnaires were filled by parents in case of 6-10 years and by students themselves in children above 10 years. We had different questionnaires for parents and students. The student questionnaire contained 9 questions while the parent questionnaire contained 10 questions. Questions 1 to 7 were related to asthma; we assigned a “1” for each “sometimes” or “a lot” response and add the scores. The total score 3 or more for any student
was considered to have the asthma diagnosis. Questions 8 and 9 were related to allergic conjunctivitis and allergic rhinitis respectively and we assigned a “1” for each “sometimes” or “a lot” response and added the scores. A total score 1 or more was considered to have allergic rhinitis.

Data collected were summaries and analyzed in percentage and proportions on MS Excel.

III. RESULTS

Study population for this study was in the age group of 5 year to 11 years with mean age 7.6 ±2.06 years with slight male preponderance. Majority (66%) of children were from outer city. (Figure 1,2 & 3)

Out of total 250 children surveyed, 43 (17.2%) found to have Bronchial Asthma. (Figure 4).

![Figure 1: Age wise distribution of children](image1)

![Figure 2: Sex wise distribution of children](image2)

![Figure 3: Residence wise distribution of children](image3)

![Figure 4: Prevelance of Bronchial Asthma in children](image4)

When distribution of Bronchial Asthma cases as per age of children was observed it was found that as the age increases proportion of children with Bronchial Asthma decreases but this variation was not found significant (P>0.05). (Table 1)

When distribution of Bronchial Asthma cases was observed as per sex of children it was found that proportion of males with Bronchial Asthma were significantly (P<0.05) more than females. (Table 1)

Likewise when distribution of Bronchial Asthma cases was observed as per residence of children it was found that proportion of children with Bronchial Asthma were significantly (P<0.05) more in walled city than outer city (Table 1).

Age range = 5 years to 11 years with mean age 7.6 years

When association between Bronchial Asthma and co morbidity with Allergic Rhinitis was evaluated it was found that it was associated with Rhinitis but when association between Allergic Rhinitis and co morbidity with Bronchial Asthma was evaluated it was found that it was associated with Bronchial Asthma i.e. co morbidity of Allergic Rhinitis is more common with Bronchial Asthma than that of co morbidity of Bronchial Asthma with Allergic Rhinitis. So chances of occurring Allergic Rhinitis is significantly more with Bronchial Asthma than the chances of Bronchial Asthma with Allergic Rhinitis. (Table 2)

Chi-square between Only Allergic Rhinitis and Co morbidity with Bronchial Asthma = 1.412 with DF 1, P=0.235, LS=NS

IV. DISCUSSION

In the present study, it was found that 17.2% of children were having Bronchial asthma. Out of these 17.2% Bronchial asthma, 11.6% were with Allergic Rhinitis. Other authors had varied experience with prevalence of Bronchial Asthma like B.S. Sharma et al16 in a cross sectional survey of 3321 school going children (5-15 years) using modified ISAAC questionnaire in Jaipur city showed 7.59% children to have Asthma (2008-2009) but S.N. Gaur et al (2006)17 in a study of adults showed the prevalence of asthma among rural, urban city and urban slum population of Delhi to be 13.34%, 7.9% and 11.92%, respectively

In this surveyed population of children 20.4% were found to have allergic Rhinitis. Although Sandeep Salvi et al18 in a study of Prevalence of asthma and allergic diseases in 15,500 school children from Pune and Nagpur showed the prevalence of allergic rhinitis 9.51% in age group of 6-7 years and 12.72% in age group of 13-14 years in Nagpur and S.N. Gaur et al (2006)17 showed the prevalence of allergic
rhinitis among adult population of Delhi as 11.69% but well comparable observations were made by Abhishek Saini et al (2012) showed the prevalence of Allergic Rhinitis (AR) in school going children 4-18 years (n=1572) in urban area of Jaipur City, Rajasthan to be 33.52%. This may be due to climate of Rajasthan.

In present study Bronchial Asthma cases was observed as per residence of children it was found that proportion of children with Bronchial Asthma were significantly (P<0.05) more in walled city than outer city. Well comparable observations were made by Sandeep Salvi et al in their study showed the prevalence of bronchial asthma 5.7% in age group of 6-7 years and 4.26% in age group of 13-14 years in Nagpur.

Out of these Allergic Rhinitis cases, 56.86% were with Bronchial asthma. So chances of occurring Allergic Rhinitis is significantly more with Bronchial Asthma than the chances of Bronchial Asthma with Allergic Rhinitis (67.44% v/s 56.86%). Abhishek Saini et al (2012) showed the prevalence of Asthma as co-morbidity in children with allergic rhinitis to be 19.16% in Jaipur City and Sibbald B, Rink E et al (1991) found asthma 23.0% in adult Rhinitis cases. Present study showed more proportion of co morbidity of Bronchial Asthma with Allergic Rhinitis, that may be either because of difference in social and geographical characteristics or rising prevalence in last few years.

V. CONCLUSION

It was concluded from this study that 17.2% of children were having Bronchial asthma and 20.4% were found to have allergic Rhinitis. Co morbidity of Bronchial Asthma with Allergic Rhinitis was observed in 11.6% of these cases. It was also concluded that Bronchial Asthma was observed significantly more in males than females and children of walled city than outer city. It was also concluded form this study that chances of occurring Allergic Rhinitis is significantly more with Bronchial Asthma than the chances of Bronchial Asthma with Allergic Rhinitis.

CONFLICT

None declared till date.
